

Quad/Octal, Simultaneous Sampling, 16-Bit Analog-to-Digital Converters

FEATURES

- Simultaneously Sample Four/Eight Channels
- Selectable Operating Modes:
 High-Speed: 52kSPS Data Rate, 31mW/ch
 Low-Power: 10kSPS Data Rate, 7mW/ch
- AC Performance:
 25kHz Bandwidth
 97dB SNR
 -105dB THD
- DC Performance: 2μV/°C Offset Drift 2ppm/°C Gain Drift
- Digital Filter:
 Linear Phase Response
 Passband Ripple: ±0.005dB
 Stop Band Attenuation: 100dB
- Selectable SPI™ or Frame Sync Serial Interface
- Simple Pin-Driven Control
- Low Sampling Aperture Error
- Specified from -40°C to +105°C
- Analog Supply: 5V
- I/O Supply: 1.8V to 3.3VDigital Core Supply: 1.8V

APPLICATIONS

- 3-Phase Power Monitors
- Defibrillators and ECG Monitors
- Coriolis Flow Meters
- Vibration/Modal Analysis

DESCRIPTION

The ADS1174 (quad) and ADS1178 (octal) are multiple delta-sigma ($\Delta\Sigma$) analog-to-digital converters (ADCs) with data rates up to 52k samples-per-second (SPS), which allow synchronous sampling of four and eight channels. These devices use identical packages, and are also compatible with the high-performance 24-bit ADS1274 and ADS1278, permitting drop-in upgrades.

The delta-sigma architecture offers near ideal 16-bit ac performance (97dB SNR, -105dB THD, 1LSB linearity) combined with 0.005dB passband ripple and linear phase response.

The high-order, chopper-stabilized modulator achieves very low drift ($2\mu V/^{\circ}C$ offset, $2ppm/^{\circ}C$ gain) and low noise ($1LSB_{PP}$). The on-chip finite impulse response (FIR) filter provides a usable signal bandwidth up to 90% of the Nyquist rate with 100dB of stop band attenuation while suppressing modulator and signal out-of-band noise.

Two operating modes allow for optimization of speed and power: High-speed mode (31mW/Ch at 52kSPS), and Low-power mode (7mW/Ch at 10kSPS).

A SYNC input control pin allows the device conversions to be started and synchronized to an external event. SPI and Frame-Sync serial interfaces are supported. The device is fully specified over the extended industrial range (−40°C to +105°C) and is available in an HTQFP-64 PowerPAD™ package.

A

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

PowerPAD is a trademark of Texas Instruments.

SPI is a trademark of Motorola, Inc.

All other trademarks are the property of their respective owners.

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

ORDERING INFORMATION

For the most current package and ordering information see the Package Option Addendum at the end of this document, or see the TI web site at www.ti.com.

ABSOLUTE MAXIMUM RATINGS

over operating free-air temperature range unless otherwise noted (1)

PARAMETER	ADS1174, ADS1178	UNIT
AVDD to AGND	-0.3 to +6.0	V
DVDD, IOVDD to DGND	-0.3 to +3.6	V
AGND to DGND	-0.3 to +0.3	V
land Comment	100, Momentary	mA
Input Current	10, Continuous	mA
Analog Input to AGND	-0.3 to AVDD + 0.3	V
Digital Input or Output to DGND	-0.3 to IOVDD + 0.3	V
Maximum Junction Temperature	+150	°C
Operating Temperature Range	-40 to +125	°C
Storage Temperature Range	-60 to +150	°C

⁽¹⁾ Stresses above these ratings may cause permanent damage. Exposure to absolute maximum conditions for extended periods may degrade device reliability. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those specified is not implied.

ELECTRICAL CHARACTERISTICS

Limit specifications at $T_A = -40$ °C to +105°C. Typical specifications at $T_A = +25$ °C, AVDD = +5V, DVDD = +1.8V, IOVDD = +3.3V, $f_{CLK} = 27MHz$, VREFP = 2.5V, VREFN = 0V, and all channels active, unless otherwise noted.

Depends on MODE[1:0] and CLKDIV selection. See Table 4 (f_{CLK}/f_{DATA}). SCLK must be continuously running and limited to ratios of 1, 1/2, 1/4, and 1/8 of f_{CLK} . t_{DOHD} (DOUT hold time) and t_{DIHD} (DIN hold time) are specified under opposite worst-case conditions (digital supply voltage and ambient temperature). Under equal conditions, with DOUT connected directly to DIN, the timing margin is >4ns. Load on DOUT = 20pF.

OVERVIEW

The ADS1174 (quad) and ADS1178 (octal) are 16-bit, delta-sigma ADCs. They offer the combination of excellent linearity, low noise, and low power consumption. Figure 1 shows the block diagram. Note that both devices are the same, except the ADS1174 has four ADCs, and the ADS1178 has eight ADCs. The pinout and package of the ADS1178 are compatible with the ADS1174 (and the 24-bit ADS1274 and ADS1278), permitting drop-in expandability or upgrades. The converters are comprised of either four (ADS1174) or eight (ADS1178) advanced, 6th-order, chopper-stabilized, delta-sigma modulators followed by low-ripple, linear phase FIR filters. The modulators measure the differential input signal, V_{IN} = (AINP - AINN), against the differential reference, $V_{REF} = (VREFP - VREFN)$. The digital filters receive the modulator signal and provide a low-noise digital output.

To allow tradeoffs between speed and power, two modes of operation are supported: High-Speed and Low-Power. Table 1 summarizes the performance of each mode.

In High-Speed mode, the data rate is 52kSPS, and in Low-Power mode, the power dissipation is only 7mW/channel at 10.5kSPS.

The ADS1174/78 is configured by simply setting the appropriate I/O pins—there are no registers to program. Data are retrieved over a serial interface that supports both SPI and Frame-Sync formats. The ADS1174/78 has a daisy-chainable output and the ability to synchronize externally, so it can be used conveniently in systems requiring more than eight channels.

Figure 1. ADS1174/ADS1178 Block Diagram

Table 1. Operating Mode Performance Summary

MODE	DATA RATE (SPS)	PASSBAND (Hz)	SNR (dB)	NOISE (LSB _{PP})	POWER DISSIPATION PER CHANNEL ⁽¹⁾ (mW)
High-Speed	52,734	23,889	97	1	31
Low-Power	10,547	4,778	97	1	7

(1) Measured with all channels operating.

FUNCTIONAL DESCRIPTION

The ADS1174 and ADS1178 are 16-bit delta/sigma ADCs consisting of independent converters that digitize input signals simultaneously. The ADS1174 consists of four independent converters, while the ADS1178 has eight independent converters.

The converter is composed of two main functional blocks to perform the ADC conversions: the modulator and the digital filter. The modulator samples the input signal together with sampling the reference voltage to produce a 1's density output stream. The density of the output stream is proportional to the analog input level relative to the reference voltage. The pulse stream is filtered by the internal digital filter where the output conversion result is produced.

In operation, the signal inputs and reference inputs are sampled by the modulator at a high rate (typically 64x higher than the final output data rate). The quantization noise of the modulator is moved to a higher frequency range where the internal digital filter removes it. This process results in very low levels of noise within the signal passband.

Because the input signal is sampled at a very high rate, input signal aliasing does not occur until the input signal frequency approaches the modulator sampling rate. The high sampling rate of the modulator greatly relaxes the requirement of external antialiasing filters, thus eliminating passband phase errors that otherwise may be caused by the analog filter.

SAMPLING APERTURE MATCHING

The converters of the ADS1174/78 operate from the same CLK input. The CLK input controls the timing of the modulator sampling instant. The converter is designed so that the sampling skew (or modulator sampling aperture match) between channels is controlled. Furthermore, the digital filters are synchronized to start the convolution phase at the same modulator clock cycle. This design results in excellent phase match among the ADS1174/78 channels.

The phase match of one four-channel ADS1174 to that of another ADS1174 may not have the same degree of sampling match (the same is true for two 8-channel ADS1178s). As a result of manufacturing variations, differences in internal propagation delay of the internal CLK signal coupled with differences of the arrival of the external CLK signal to each device may cause larger sampling match errors. Equal length CLK traces or external clock distribution devices can be used to control the arrival of the CLK signals to help reduce the sampling match error.

FREQUENCY RESPONSE

The digital filter sets the overall frequency response. The filter uses a multi-stage FIR topology to provide linear phase with minimal passband ripple and high stop band attenuation. The oversampling ratio of the digital filter (that is, the ratio of the modulator sampling to the output data rate: f_{MOD}/f_{DATA}) is 64 for both High-Speed and Low-Power modes.

Figure 2 shows the frequency response of the ADS1174/78 normalized to f_{DATA} . Figure 3 shows the passband ripple. The transition from passband to stop band is illustrated in Figure 4. The overall frequency response repeats at 64x multiples of the modulator frequency f_{MOD} , as shown in Figure 5.

Figure 2. Frequency Response

Figure 3. Passband Response

Figure 4. Transition Band Response

Figure 5. Frequency Response Out to f_{MOD}

These image frequencies, if present in the signal and not externally filtered, fold back (or alias) into the passband, causing errors. Table 2 lists the degree of image rejection versus external antialiasing filter order. The stop band of the ADS1174/78 provides 100dB attenuation of frequencies that begin just beyond the passband and continue out to f_{MOD} . Placing an antialiasing, low-pass filter in front of the ADS1174/78 inputs is recommended to limit possible high-amplitude, out-of-band signals and noise.

Table 2. Antialiasing Filter Order Image Rejection

ANTIALIASING FILTER ORDER	IMAGE REJECTION (dB) (f _{-3dB} at f _{DATA})
1	39
2	75
3	111

PHASE RESPONSE

The ADS1174/78 incorporates a multiple stage, linear phase digital filter. Linear phase filters exhibit constant delay time versus input frequency (constant group delay), which means the time delay from any instant of the input signal to the same instant of the output data is constant, and is independent of input signal frequency. This behavior results in essentially zero phase errors when analyzing multi-tone signals.

SETTLING TIME

As with frequency and phase response, the digital filter also determines settling time. Figure 6 shows the output settling behavior after a step change on the analog inputs normalized to conversion periods. The X-axis is given in units of conversion. Note that after the step change on the input occurs, the output data change very little prior to 30 conversion periods. The output data are fully settled after 76 conversion periods.

Figure 6. Step Response

ANALOG INPUTS (AINP, AINN)

The ADS1174/78 measures each differential input signal $V_{\rm IN} = ({\sf AINP} - {\sf AINN})$ against the common differential reference $V_{\rm REF} = ({\sf VREFP} - {\sf VREFN})$. The most positive measurable differential input is $+V_{\rm REF}$, which produces the most positive digital output code of 7FFFh. Likewise, the most negative measurable differential input is $-V_{\rm REF}$, which produces the most negative digital output code of 8000h.

For optimal performance, drive the ADS1174/78 inputs differentially. For single-ended input applications, one of the inputs (AINP or AINN) can be driven while the other input is fixed (typically, to AGND or +2.5V); fixing the input to +2.5V permits bipolar operation, thereby using the full range of the converter.

While the ADS1174/78 measures the differential input signal, the absolute input voltage is also important. This is the voltage on either input (AINP or AINN) with respect to AGND. The range for this voltage is:

$$-0.1V < (AINN or AINP) < AVDD + 0.1V$$

If either input is taken below -0.4V or above (AVDD + 0.4), ESD protection diodes on the inputs may turn on.

If these conditions are possible, external Schottky clamp diodes or series resistors may be required to limit the input current to safe levels (see Absolute Maximum Ratings table).

The ADS1174/78 is a high-performance ADC. For optimum performance, it is critical that the appropriate circuitry be used to drive the ADS1174/78 inputs. See the *Applications Information* section for the recommended circuits.

The ADS1174/78 uses switched-capacitor circuitry to measure the input voltage. Internal capacitors are charged by the inputs and then discharged. Figure 7 shows a conceptual diagram of these circuits. Switch S_2 represents the net effect of the modulator circuitry in discharging the sampling capacitor; the actual implementation is different. The timing for switches S_1 and S_2 is shown in Figure 8. The sampling time (t_{SAMPLE}) is the inverse of modulator sampling frequency (f_{MOD}) and is a function of the mode, the CLKDIV input, and frequency of CLK, as shown in Table 3.

The average load presented by the switched capacitor input can be modeled with an effective differential impedance, as shown in Figure 9. Note that the effective impedance is a function of f_{MOD} .

Low-Power	1	f _{CLK} /40
Low-Power	0	f _{CLK} /8

Figure 9. Effective Input Impedances

VOLTAGE REFERENCE INPUTS (VREFP, VREFN)

The voltage reference for the ADS1174/78 ADC is the differential voltage between VREFP and VREFN: $V_{REF} = (VREFP - VREFN)$. The voltage reference is common to all channels. The reference inputs use a structure similar to that of the analog inputs with the equivalent circuitry on the reference inputs shown in Figure 10. As with the analog inputs, the load presented by the switched capacitor can be modeled with an effective impedance, as shown in Figure 11. However, the reference input impedance depends on the number of active (enabled) channels in addition to f_{MOD}. As a result of the change of reference input impedance caused by enabling and disabling channels, the regulation and settling time of the external reference should be noted, so as not to affect the readings of other channels.

Figure 10. Equivalent Reference Input Circuitry

Figure 11. Effective Reference Impedance

ESD diodes protect the reference inputs. To keep these diodes from turning on, make sure the voltages on the reference pins do not go below AGND by more than 0.4V, and likewise do not exceed AVDD by 0.4V.

If these conditions are possible, external Schottky clamp diodes or series resistors may be required to limit the input current to safe levels (see Absolute Maximum Ratings table).

Note that the valid operating range of the reference inputs is limited to the following:

 $-0.1V \le VREFN \le 0.1V$

VREFN + 0.5V ≤ VREFP ≤ VREFN + 3.1V

A high-quality reference voltage with the appropriate drive strength is essential for achieving the best performance from the ADS1174/78. Noise and drift on the reference degrade overall system performance. See the *Application Information* section for example reference circuits.

CLOCK INPUT (CLK)

The ADS1174/78 requires a clock input for operation. Each ADS1174/78 converter operates from the same clock input. At the maximum data rate, the clock input can be either 27MHz or 13.5MHz (5.4MHz, low-power mode), determined by the setting of the CLKDIV input. The selection of the external clock frequency (f_{CLK}) does not affect the resolution (the oversampling ratio, OSR, remains fixed) or power dissipation of the ADS1174/78. However, a slower f_{CLK} can reduce the power consumption of an external clock driver. The output data rate scales with clock frequency, down to a minimum clock frequency of f_{CLK} = 100kHz. Table 4 summarizes the ratio of clock input frequency (f_{CLK}) to (f_{DATA}), maximum data rate and rate corresponding maximum clock input for the two operating modes.

Table 4. Clock Input Options

MODE SELECTION	f _{CLK} (MHz)	CLKDIV	f _{CLK} /f _{DATA}	DATA RATE (SPS)
High Chood	27	1	512	52,734
High-Speed	13.5	0	256	52,754
Low-Power	27	1	2,560	10.547
Low-Power	5.4	0	512	10,547

As with any high-speed data converter, a high-quality, low-jitter clock is essential for optimum performance. Crystal clock oscillators are the recommended clock source. Make sure to avoid excess ringing on the clock input; keeping the clock trace as short as possible using a 50Ω series resistor, placed close to the source end, often helps.

MODE SELECTION (MODE)

The ADS1174/78 supports two modes of operation: High-Speed and Low-Power. These modes offer optimization of speed and power. The mode selection is determined by the status of the digital input MODE pins, as shown in Table 5. The ADS1174/78 constantly monitors the status of the MODE pin during operation.

Table 5. Mode Selection

MODE	MODE SELECTION	MAX f _{DATA} ⁽¹⁾
0	High-Speed	52,734
1	Low-Power	10,547

(1) $f_{CLK} = 27MHz$ (CLKDIV = 1).

When using the SPI protocol, \overline{DRDY} is held high after a mode change occurs until settled (or valid) data are ready, as shown in Figure 12 and Table 6.

In Frame-Sync protocol, the DOUT pins are held low after a mode change occurs until settled data are ready, as shown in Figure 12 and Table 6. Data can be read from the device to detect when DOUT changes to logic 1, indicating valid data.

SYNCHRONIZATION (SYNC)

The ADS1174/78 can be synchronized by pulsing the SYNC pin low and then returning the pin high. When the pin goes low, the conversion process stops, and the internal counters used by the digital filter are reset. When the SYNC pin returns high, the conversion process restarts. Synchronization allows the conversion to be aligned with an external event, such as a reference timing pulse.

Since the converters of the ADS1174/78 operate in parallel from the same master clock and use the same SYNC input control, they are, by default, in synchronization with each other. However, the synchronization of multiple ADS1174/78s is somewhat different. At device power-on, variations in internal reset thresholds from device to device may result in uncertainty in conversion timing.

The SYNC pin can be used to synchronize multiple ADS1174/78s to within the same CLK cycle. Figure 13 illustrates the timing requirement of SYNC and CLK in SPI format.

See Figure 14 for the Frame-Sync format timing requirement.

Figure 12. Mode Change Timing

Table 6. Mode Change

SYMBOL	DESCRIPTION	MIN	TYP	MAX	UNITS
t _{NDR-SPI}	Time for new data to be ready (SPI)			129	Conversions (1/f _{DATA})
t _{NDR-FS}	Time for new data to be ready (Frame-Sync)	127		128	Conversions (1/f _{DATA})

After synchronization, indication of valid data depends on the whether SPI or Frame-Sync format is used.

In the SPI format, \overline{DRDY} goes high as soon as \overline{SYNC} is taken low; see Figure 13. After \overline{SYNC} is returned high, \overline{DRDY} stays high while the digital filter is settling. Once valid data are ready for retrieval, \overline{DRDY} goes low.

In the Frame-Sync format, DOUT goes low <u>as soon</u> as <u>SYNC</u> is taken low; see <u>Figure 14</u>. After <u>SYNC</u> is returned high, DOUT stays low while the digital filter is settling. Once valid data are ready for retrieval, DOUT begins to output valid data. For proper synchronization, <u>FSYNC</u>, <u>SCLK</u>, and CLK must be established before taking <u>SYNC</u> high, and must then remain running.

POWER-DOWN (PWDN)

The ADS1174/78 measurement channels can be independently powered down by use of the \overline{PWDN} inputs. To enter the power-down mode, hold the respective PWDN pin low for at least two f_{CLK} cycles. To exit power-down, return the corresponding PWDN pin high. Note that when all channels are powered down, the ADS1174/78 enters a microwatt (μW) power state where all internal biasing is powered down. In this event, the TEST[1:0] input pins must be driven; all other input pins can float (the ADS1174/78 outputs remain driven).

As shown in Figure 15 and Table 9, a maximum of 130 conversion cycles (SPI interface) or 129 conversion cycles (Frame-Sync interface) must elapse before reading data after exiting power-down. Data from channels already running are not affected. The user software can perform the required delay time in the following ways:

1. Count the number of data conversions after taking the PWDN pin high.

- Wait for 130/f_{DATA} (SPI) or 129/f_{DATA} (Frame-Sync) after taking the PWDN pins high.
- Detect for non-zero data in the powered-up channel.

After powering up one or more channels, the channels are synchronized to each other. It is not necessary to use the SYNC pin to synchronize them.

When a channel is powered down in TDM data format, the data for the powered-down channel are either forced to zero (fixed-position TDM data mode) or replaced by shifting the data from the next channel into the vacated data position (dynamic-position TDM data mode).

In discrete data format, the data are always forced to zero. When powering-up a channel in dynamic-position TDM data format mode, the channel data remain packed until the data are ready, at which time the data frame is expanded to include the just-powered channel data. See the *Data Format* section for details.

Figure 15. Power-Down Timing

Table 9. Power-Down Timing

SYMBOL	DESCRIPTION	MIN	TYP	MAX	UNITS
t _{PDWN}	PDWN pulse width to enter Power-Down mode	2			CLK periods
4	Time for new data to be ready (SPI)	129		130	Conversions (1/f _{DATA})
^I NDR	Time for new data to be ready (Frame-Sync)	128		129	Conversions (1/f _{DATA})

FORMAT[2:0]

Data can be read from the ADS1174/78 with two serial interface protocols (SPI or Frame-Sync) and several options of data formats (TDM/Discrete and Fixed/Dynamic data positions). The FORMAT[2:0] inputs are used to select among the options. Table 10 lists the available options. See the DOUT Modes section for details of the DOUT modes and data positions.

Table 10. Data Output Format

FORMAT[2:0]	INTERFACE PROTOCOL	DOUT MODE	DATA POSITION
000	SPI	TDM	Dynamic
001	SPI	TDM	Fixed
010	SPI	Discrete	_
011	Frame-Sync	TDM	Dynamic
100	Frame-Sync	TDM	Fixed
101	Frame-Sync	Discrete	_

DATA FORMAT

The ADS1174/78 outputs 16 bits of data in two's complement format.

A positive full-scale input produces an ideal output code of 7FFFh, and the negative full-scale input produces an ideal output code of 8000h. The output clips at these codes for signals exceeding full-scale. Table 11 summarizes the ideal output codes for different input signals.

Table 11. Ideal Output Code versus Input Signal

INPUT SIGNAL V _{IN} (AINP – AINN)	IDEAL OUTPUT CODE ⁽¹⁾					
≥ +V _{REF}	7FFFh					
+ V _{REF} 2 ¹⁵ - 1	0001h					
0	0000h					
$\frac{-V_{REF}}{2^{15}-1}$	FFFFh					
$\leq -V_{REF} \left(\frac{2^{15}}{2^{15} - 1} \right)$	8000h					

⁽¹⁾ Excludes effects of noise, INL, offset, and gain errors.

SERIAL INTERFACE PROTOCOLS

Data are retrieved from the ADS1174/78 using the serial interface. Two protocols are available: SPI and Frame-Sync. The <u>same</u> pins are used for both interfaces: SCLK, DRDY/FSYNC, DOUT[4:1] (or DOUT[8:1] for the ADS1178), and DIN. The FORMAT[2:0] pins select the desired interface protocol.

SPI SERIAL INTERFACE

The SPI-compatible format is a simple read-only interface. Data ready for retrieval are indicated by the falling DRDY output and are shifted out on the falling edge of SCLK, MSB first. The interface can be daisy-chained using the DIN input when using multiple ADS1174/78s. See the *Daisy-Chaining* section for more information.

SCLK

The serial clock (SCLK) features a Schmitt-triggered input and shifts out data on DOUT on the falling edge. It also shifts in data on the falling edge on DIN when this pin is being used for daisy-chaining. The device shifts data out on the falling edge and the user typically shifts this data in on the rising edge. Even though the SCLK input has hysteresis, it is recommended to keep SCLK as clean as possible to prevent glitches from accidentally shifting the data. SCLK may be run as fast as the CLK frequency. SCLK may be either in free-running or stop-clock conversions. For operation between performance, use f_{SCLK}/f_{CLK} ratios of 1, 1/2, 1/4, 1/8, etc. NOTE: One CLK period is required after DRDY falls, to start shifting data (see Timing Requirements: SPI Format).

DRDY/FSYNC (SPI Format)

In the SPI format, this pin functions as the \overline{DRDY} output. It goes low when data are ready for retrieval and then returns high on the falling edge of the first subsequent SCLK. If data are not retrieved (that is, SCLK is held low), \overline{DRDY} pulses high just before the next conversion data are ready, as shown in Figure 16. The new data are loaded within one CLK cycle before \overline{DRDY} goes low. All data must be shifted out before this time to avoid being overwritten.

Figure 16. DRDY Timing with No Readback

DOUT

In Discrete Data Output mode, the conversion data are output on the individual DOUT pins (DOUT1, DOUT2, etc.), whereas in TDM mode, data are output only on DOUT1. The MSB data are valid on DOUT[4:1]/[8:1] when DRDY goes low. The subsequent bits are shifted out with each falling edge of SCLK. If daisy-chaining (TDM mode), the data shifted in using DIN appear on DOUT1 after all channel data have been shifted out.

DIN

This input is used when multiple ADS1174/78s are to be daisy-chained together. The DOUT1 pin of the first device connects to the DIN pin of the next, etc. It can be used with either the SPI or Frame-Sync formats. Data are shifted in on the falling edge of SCLK. When using only one ADS1174/78, tie DIN low. See the Daisy-Chaining section for more information.

FRAME-SYNC SERIAL INTERFACE

Frame-Sync format is similar to the interface often used on audio ADCs. It operates in slave fashion—the user must supply framing signal FSYNC (similar to the *left/right clock* on stereo audio ADCs) and the serial clock SCLK (similar to the *bit clock* on audio ADCs). The data is output MSB first or *left-justified*. When using Frame-Sync format, the FSYNC and SCLK inputs must be continuously running with the required relationships shown in the Frame-Sync Timing Requirements.

SCLK

The serial clock (SCLK) features a Schmitt-triggered input and shifts out data on DOUT on the falling edge. It also shifts in data on the falling edge on DIN when this pin is being used for daisy-chaining. Even though SCLK has hysteresis, it is recommended to keep SCLK as clean as possible to prevent glitches from accidentally shifting the data. When using Frame-Sync format, SCLK must run continuously; if SCLK is disabled or interrupted, the data readback

will be corrupted. The number of SCLKs within a frame period (FSYNC clock) can be any power of two ratio of clock cycles (1, 1/2, 1/4, etc.), as long as the number of cycles is sufficient to shift the data output from all channels within one data frame.

DRDY/FSYNC (Frame-Sync Format)

In Frame-Sync format, this pin is used as the FSYNC input. The frame-sync input (FSYNC) sets the frame period which must be same as the data rate. The required number of f_{CLK} cycles to each FSYNC period depends on the mode selection and the CLKDIN input. Table 4 indicates the number of CLK cycles to each frame (f_{CLK}/f_{DATA}). If the FSYNC period is not the proper value, data readback is corrupted.

DOUT

In Discrete Data Output mode, the conversion data are shifted out on the individual DOUT pins (DOUT1, DOUT2, etc.), whereas in TDM mode, data are output only on DOUT1. The MSB data become valid on DOUT[4:1]/[8:1] on the SCLK rising edge prior to FSYNC going high. The subsequent bits are shifted out with each falling edge of SCLK. If daisy-chaining (TDM mode), the data shifted in using DIN appear on DOUT1 after all channel data have been shifted out (that is, 4 channels × 16 bits per channel = 64 bits for the ADS1174, and 8 channels × 16 bits per channel = 128 bits for the ADS1178).

DIN

This input is used when multiple ADS1174/78s are to be daisy-chained together. It can be used with either SPI or Frame-Sync formats. Data are shifted in on the falling edge of SCLK. When using only one ADS1174/78, tie DIN low. See the *Daisy-Chaining* section for more information.

DOUT MODES

For both SPI and Frame-Sync interface protocols, either the data are shifted out through individual channel DOUT pins in a parallel data format (Discrete mode), or the data for all channels are shifted out in series through common pin DOUT1 (TDM mode).

TDM Mode

In time division multiplexed (TDM) data output mode, the data for all channels are shifted out, in series, on a single pin (DOUT1). As shown in Figure 17, the data from channel 1 are shifted out first, followed by channel 2 data, etc. After the data from the last channel are shifted out (channel 4 for the ADS1174 or channel 8 for the ADS1178), the data from the DIN input follow. DIN is used to daisy-chain the data

output from another ADS1174, ADS1178, or other compatible device. Note that when all channels of the ADS1174/78 are powered down, the interface is powered down, rendering the DIN input powered down as well. When one or more channels of the device are powered down, the data format of the TDM mode can be fixed or dynamic.

TDM Mode, Fixed-Position Data

In this TDM data output mode, the data position of the channels remains fixed, regardless of whether channels are disabled. If a channel is powered down, data are forced to zero, but occupy the same position within the data stream. Figure 18 shows the data stream with channel 1 and channel 3 powered down.

Figure 17. TDM Mode (All Channels Enabled)

Figure 18. TDM Mode, Fixed-Position Data (Channels 1 and 3 Shown Powered Down)

TDM Mode, Dynamic Position Data

In this TDM data output mode, when a channel is powered down, the data from higher channels shift one position in the data stream to fill the vacated data slot. Figure 19 shows the data stream with channel 1 and channel 3 powered down.

Discrete Data Output Mode

In Discrete data output mode, the channel data are shifted out in parallel using individual channel data output pins DOUT[4:1] for the ADS1174, or DOUT[8:1] for the ADS1178. After the 16th SCLK, the channel data are forced to zero. The data are also forced to zero for powered-down channels. Figure 20 depicts the data format.

Figure 19. TDM Mode, Dynamic Position Data (Channels 1 and 3 Shown powered Down)

Figure 20. Discrete Data Output Mode

DAISY-CHAINING

Multiple ADS1174/78s can be daisy-chained together to simplify the serial interface connections. The DOUT1 data output pin of one ADS1174/78 is connected to the DIN input of the next ADS1174/78. As Figure 21 illustrates, the DOUT1 pin of device 1 provides the output data to a controller, and the DIN input of device 2 is grounded. Figure 22 describes the data format when reading data back in a daisy-chain configuration.

The maximum number of channels that may be daisy-chained in this way is limited by the frequency of f_{SCLK} , the mode selection, and the CLKDIV input. The frequency of f_{SCLK} must be high enough to completely shift the data out from all channels within one f_{DATA} period. Table 12 lists the maximum number of daisy-chained channels when $f_{SCLK} = f_{CLK}$.

Figure 21. Daisy-Chaining of Two ADS1178s, SPI Protocol (FORMAT[2:0] = 000 or 001)

Figure 22. Daisy-Chain Data Format of Figure 21

Table 12. Maximum Channels in a Daisy-Chain ($f_{SCLK} = f_{CLK}$)

MODE SELECTION	CLKDIV	MAXIMUM NUMBER OF CHANNELS
High Speed	1	32
High-Speed	0	16
Low Power	1	160
Low-Power	0	32

To increase the number of data channels possible in a chain, a segmented DOUT scheme may be used, producing two data streams. Figure 23 illustrates four ADS1178s, with a pair of ADS1178s daisy-chained together. The channel data of each daisy-chained pair are shifted out in parallel and are received by the processor through independent data channels.

Whether the interface protocol is SPI or Frame-Sync, it is recommended to synchronize all devices by tying the SYNC inputs together. When synchronized in SPI protocol, it is only necessary to monitor the DRDY output of one ADS1178.

In Frame-Sync interface protocol, the data from all devices are ready on the rising edge of FSYNC.

Since DOUT1 and DIN are both shifted on the falling edge of SCLK, the propagation delay on DOUT1 creates a setup time for DIN. Minimize the skew in SCLK to avoid timing violations.

Figure 23. Segmented DOUT Daisy-Chain, Frame-Sync Protocol (FORMAT[2:0] = 011 or 100)

POWER SUPPLIES

The ADS1174/78 has three power supplies: AVDD, DVDD, and IOVDD. AVDD is the analog supply that powers the modulator, DVDD is the digital supply that powers the digital core, and IOVDD is the digital I/O power supply. The IOVDD and DVDD power supplies can be tied together if desired (+1.8V). To achieve rated performance, it is critical that the power supplies are bypassed with $0.1\mu F$ and $10\mu F$ capacitors placed as close as possible to the supply pins. A single $10\mu F$ ceramic capacitor may be substituted in place of the two capacitors.

Figure 24 shows the start-up sequence of the ADS1174/78. At power-on, bring up the DVDD supply first, followed by IOVDD and then AVDD. Check the power-supply sequence for proper order, including the ramp rate of each supply. DVDD and IOVDD may

be sequenced at the same time if the supplies are tied together. Each supply has an internal reset circuit whose outputs are summed together to generate a global power-on reset. After the supplies have exceeded the reset thresholds, 2¹⁸ f_{CLK} cycles are counted before the converter initiates the conversion process. Following the CLK cycles, the data for 129 conversions are suppressed by the ADS1174/78 to allow output of fully-settled data. In SPI protocol, DRDY is held high during this interval. In frame-sync protocol, DOUT is forced to zero. The power supplies should be applied before any analog or digital pin is driven. For consistent performance, assert SYNC after device power-on when data first appear.

(1) The power-supply reset thresholds are approximate.

Figure 24. Start-Up Sequence

PIN TEST USING TEST[1:0] INPUTS

Test mode allows continuity testing of the digital I/O pins. In this mode, the normal functions of the digital pins are disabled and routed to each other as pairs through internal logic, as shown in Table 13. Note that some of the digital input pins become outputs; this configuration should be taken into account when using test mode.

Table 13. Test Mode Pin Map (TEST[1:0] = 11)

TEST MODE PIN MAP ⁽¹⁾								
INPUT PINS	OUTPUT PINS							
PWDN1	DOUT1							
PWDN2	DOUT2							
PWDN3	DOUT3							
PWDN4	DOUT4							
PWDN5 (2)	DOUT5 ⁽²⁾							
PWDN6 (2)	DOUT6 ⁽²⁾							
PWDN7 (2)	DOUT7 ⁽²⁾							
PWDN8 (2)	DOUT8 ⁽²⁾							
MODE	DIN							
FORMAT0	CLKDIV							
FORMAT1	DRDY/FSYNC							
FORMAT2	SCLK							

The CLK input does not have a test output; SYNC = 1 and is an output.

The analog input, power supply, and ground pins remain connected as normal. The test mode is engaged by the setting the pins TEST[1:0] = 11. For normal converter operation, set TEST[1:0] = 00.

VCOM OUTPUT

The VCOM pin is an analog output of approximately AVDD/2. This voltage may be used to set the common-mode voltage of the input buffers. The drive capability of this output is limited; most cases require an external buffer to minimize loading. A $0.1\mu F$ capacitor to AGND is recommended to reduce noise pick-up.

Figure 25. VCOM Output

⁽²⁾ ADS1178 only.

APPLICATION INFORMATION

To obtain the specified performance from the ADS1174/78, the following layout and component guidelines should be considered.

- 1. Power Supplies: The device requires three power supplies for operation: DVDD, IOVDD, and AVDD. The range for DVDD is 1.65V to 1.95V; the range of IOVDD is 1.65V to 3.6V; and AVDD is restricted to 4.75V to 5.25V. For all supplies, use a 10μF tantalum capacitor, bypassed with a 0.1μF ceramic capacitor, placed close to the device pins. Alternatively, a single 10μF ceramic capacitor can be used. The supplies should be relatively free of noise and should not be shared with devices that produce voltage spikes (such as relays, LED display drivers, etc.). If a switching power-supply source is used, the voltage ripple should be low (< 2mV) and the switching frequency outside the passband of the converter.</p>
- Ground Plane: A single ground plane connecting both AGND and DGND pins can be used. If separate digital and analog grounds are used, connect the grounds together at the converter, or at the power entry point of the printed circuit board (PCB).
- 3. **Digital Inputs:** It is recommended to source-terminate the digital inputs to the device with 50Ω series resistors. The resistors should be placed close to the driving end of the digital source (oscillator, logic gates, DSP, etc.) This placement helps to reduce ringing on the digital lines, which may lead to degraded ADC performance.
- 4. Analog/Digital Circuits: Place analog circuitry (input buffer, reference) and associated tracks together, keeping them away from digital circuitry (DSP, microcontroller, logic). Avoid crossing digital tracks across analog tracks to reduce noise coupling and crosstalk.

- 5. **Reference Inputs:** It is recommended to use either a minimum $10\mu\text{F}$ tantalum with a $0.1\mu\text{F}$ ceramic capacitor, or a single $1\mu\text{F}$ ceramic capacitor, directly across the reference inputs, VREFP and VREFN. The reference input should be driven by a low-impedance source. For best performance, the reference should be low-noise.
- 6. Analog Inputs: The analog input pins must be driven differentially to achieve specified performance. A true differential driver or transformer (for ac applications) can be used for this purpose. Route the analog inputs tracks (AINP, AINN) as a pair from the buffer to the converter using short, direct tracks and away from digital tracks.
 - A 1nF to 10nF capacitor should be used directly across the analog input pins, AINP and AINN. A low-k dielectric (such as COG or film type) should be used to maintain low THD. Capacitors from each analog input to ground can be used. They should be no larger than 1/10 the size of the difference capacitor (typically 100pF) to preserve the AC common-mode performance.
- 7. Component Placement: Place the power supply, analog input, and reference input bypass capacitors as close as possible to the device pins. This layout is particularly important for the small-value ceramic capacitors. Surface-mount components are recommended to avoid the higher inductance of leaded components.

Figure 26 to Figure 28 illustrate basic connections and interfaces that can be used with the ADS1174/78.

- (1) External Schottky clamp diodes or series resistors may be needed to prevent overvoltage on the inputs. See the Analog Inputs section.
- (2) Indicates ceramic capacitors.
- (3) Indicates COG ceramic capacitors.
- (4) For pin test mode, set to logic high.
- (5) The op amp and input RC components filter the REF1004 noise.

POWERPAD THERMALLY-ENHANCED PACKAGING

The PowerPAD concept is implemented in standard epoxy resin package material. The integrated circuit is attached to the leadframe die pad using thermally conductive epoxy. The package is molded so that the leadframe die pad is exposed at a surface of the package. This exposure provides an extremely low thermal resistance to the path between the IC junction and the exterior case. The external surface of the leadframe die pad is located on the PCB side of the package, allowing the die pad to be attached to

the PCB using standard flow soldering techniques. This soldering allows efficient attachment to the PCB and permits the board structure to be used as a heat-sink for the package. Using a thermal pad identical in size to the die pad and vias connected to the PCB ground plane, the board designer can now implement power packaging without additional thermal hardware (for example, external heat sinks) or the need for specialized assembly instructions.

Figure 29 illustrates a cross-section view of a PowerPAD package.

Figure 29. Cross-Section View of a PowerPAD Thermally-Enhanced Package

PowerPAD PCB Layout Considerations for the ADS1174/78

Figure 30 shows the recommended layer structure for thermal management when using a PowerPad package on a 4-layer PCB design. Note that the thermal pad is placed on both the top and bottom sides of the board. The ground plane is used as the heat-sink, while the power plane is thermally isolated from the thermal vias.

Figure 31 shows the required thermal pad etch pattern for the 64-lead HTQFP package used for the ADS1174/78. Nine 13mil (0.33mm) thermal vias plated with one ounce of copper are placed within the thermal pad area for the purpose of connecting the pad to the ground plane layer. The ground plane is used as a heatsink in this application. It is very important that the thermal via diameter be no larger than 13mils in order to avoid solder wicking during the reflow process. Solder wicking results in thermal voids that reduce heat dissipation efficiency and hamper heat flow away from the IC die.

The via connections to the thermal pad and internal ground plane should be plated completely around the hole, as opposed to the typical web or spoke thermal relief connection. Plating entirely around the thermal via provides the most efficient thermal connection to the ground plane.

Additional PowerPAD Package Information

Texas Instruments publishes the PowerPAD Thermally-Enhanced Package Application Report (TI literature number SLMA002), available for download at www.ti.com, which provides a more detailed discussion of PowerPAD design and layout considerations. Before attempting a board layout with the ADS1174/78, it is recommended that the hardware engineer and/or layout designer be familiar with the information contained in this document.

⁽¹⁾ The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check http://www.ti.com/productcontent for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

⁽³⁾ MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

PowerPAD™ PLASTIC QUAD FLATPACK

THERMAL INFORMATION

This PowerPAD™ package incorporates an exposed thermal pad that is designed to be attached to a printed circuit board (PCB). The thermal pad must be soldered directly to the PCB. After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For additional information on the PowerPAD package and how to take advantage of its heat dissipating abilities, refer to Technical Brief, PowerPAD Thermally Enhanced Package, Texas Instruments Literature No. SLMA002 and Application Brief, PowerPAD Made Easy, Texas Instruments Literature No. SLMA004. Both documents are available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

NOTES: A. All linear dimensions are in millimeters

PAP (S-PQFP-G64)

PowerPAD™ PLASTIC QUAD FLATPACK

NOTES:

- A. All linear dimensions are in millimeters.
- B. This drawing is subject to change without notice.
- C. Customers should place a note on the circuit board fabrication drawing not to alter the center solder mask defined pad.
- D. This package is designed to be soldered to a thermal pad on the board. Refer to Technical Brief, PowerPad Thermally Enhanced Package, Texas Instruments Literature No. SLMA002, SLMA004, and also the Product Data Sheets for specific thermal information, via requirements, and recommended board layout. These documents are available at www.ti.com http://www.ti.com. Publication IPC-7351 is recommended for alternate designs.
- E. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Example stencil design based on a 50% volumetric metal load solder paste. Refer to IPC-7525 for other stencil recommendations.
- F. Customers should contact their board fabrication site for solder mask tolerances between and around signal pads.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
