## 42V, 1.0A Step-Down Switching Regulator

### General Description

The LM25010 features all the functions needed to implement a low cost, efficient, buck regulator capable of supplying in excess of 1A load current. This high voltage regulator integrates an N-Channel Buck Switch, and is available in thermally enhanced LLP-10 and TSSOP-14EP packages. The constant on-time regulation scheme requires no loop compensation resulting in fast load transient response and simplified circuit implementation. The operating frequency remains constant with line and load variations due to the inverse relationship between the input voltage and the on-time. The valley current limit detection is set at 1.25A. Additional features include: VCC under-voltage lock-out, thermal shutdown, gate drive under-voltage lock-out, and maximum duty cycle limiter.

### Features

- Wide 6V to 42V Input Voltage Range
- Valley Current Limiting At 1.25A
- Programmable Switching Frequency Up To 1 MHz
- Integrated N-Channel Buck Switch
- Integrated High Voltage Bias Regulator
- No Loop Compensation Required
- Ultra-Fast Transient Response
- Nearly Constant Operating Frequency With Line and Load Variations
- Adjustable Output Voltage
- 2.5V,  $\pm 2\%$  Feedback Reference
- Programmable Soft-Start
- Thermal shutdown
- LM25010Q is AEC-Q100 Grade 1 & 0 qualified

### Typical Applications

- Non-Isolated Telecommunications Regulator
- Secondary Side Post Regulator
- Automotive Electronics

### Package

- LLP-10 (4 mm x 4 mm)
- TSSOP-14EP
- Both Packages Have Exposed Thermal Pad For Improved Heat Dissipation

### Basic Step-Down Regulator

\*Automotive Grade (Q) product incorporates enhanced manufacturing and support processes for the automotive market, including defect detection methodologies. Reliability qualification is compliant with the requirements and temperature grades defined in the AEC-Q100 standard. Automotive grade products are identified with the letter Q. For more information go to <http://www.national.com/automotive>.

## Pin Descriptions

Pin Number		Name	Description	Application Information
LLP-10	TSSOP-14			
1	2	SW	Switching Node	Internally connected to the buck switch source. Connect to the inductor, free-wheeling diode, and bootstrap capacitor.
2	3	BST	Boost pin for bootstrap capacitor	Connect a capacitor from SW to the BST pin. The capacitor is charged from VCC via an internal diode during the buck switch off-time.
3	4	ISEN	Current sense	During the buck switch off-time, the inductor current flows through the internal sense resistor, and out of the ISEN pin to the free-wheeling diode. The current limit comparator keeps the buck switch off if the ISEN current exceeds 1.25A (typical).
4	5	SGND	Current Sense Ground	Re-circulating current flows into this pin to the current sense resistor.
5	6	RTN	Circuit Ground	Ground return for all internal circuitry other than the current sense resistor.
6	9	FB	Voltage feedback input from the regulated output	Input to both the regulation and over-voltage comparators. The FB pin regulation level is 2.5V.
7	10	SS	Softstart	An internal 11.5 $\mu$ A current source charges the SS pin capacitor to 2.5V to soft-start the reference input of the regulation comparator.
8	11	RON/SD	On-time control and shutdown	An external resistor from VIN to the RON/SD pin sets the buck switch on-time. Grounding this pin shuts down the regulator.
9	12	VCC	Output of the bias regulator	The voltage at VCC is nominally equal to $V_{IN}$ for $V_{IN} < 8.9V$ , and regulated at 7V for $V_{IN} > 8.9V$ . Connect a 0.47 $\mu$ F, or larger capacitor from VCC to ground, as close as possible to the pins. An external voltage can be applied to this pin to reduce internal dissipation if $V_{IN}$ is greater than 8.9V. MOSFET body diodes clamp VCC to VIN if $V_{CC} > V_{IN}$ .
10	13	VIN	Input supply voltage	Nominal input range is 6V to 42V. Input bypass capacitors should be located as close as possible to the VIN pin and RTN pins.
	1,7,8,14	NC	No connection.	No internal connection. Can be connected to ground plane to improve heat dissipation.
		EP	Exposed Pad	Exposed metal pad on the underside of the device. It is recommended to connect this pad to the PC board ground plane to aid in heat dissipation.

**Absolute Maximum Ratings** (Note 1)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

VIN to RTN	-0.3V to 45V
BST to RTN	-0.3V to 59V
SW to RTN (Steady State)	-1.5V
BST to VCC	45V
BST to SW	14V
VCC to RTN	-0.3V to 14V
SGND to RTN	-0.3V to +0.3V
SS to RTN	-0.3V to 4V

VIN to SW	45V
All Other Inputs to RTN	-0.3V to 7V
ESD Rating (Note 2)	
Human Body Model	2kV
Storage Temperature Range	-65°C to +150°C
Lead Temperature (Soldering 4 sec) (Note 4)	260°C

**Operating Ratings** (Note 1)

VIN Voltage	6.0V to 42V
Junction Temperature	
LM25010/LM25010Q1	-40°C to + 125°C
LM25010Q0	-40°C to + 150°C

**Electrical Characteristics** Specifications with standard type are for  $T_J = 25^\circ\text{C}$  only; limits in boldface type apply over the full Operating Junction Temperature ( $T_J$ ) range. Minimum and Maximum limits are guaranteed through test, design, or statistical correlation. Typical values represent the most likely parametric norm at  $T_J = 25^\circ\text{C}$ , and are provided for reference purposes only. Unless otherwise stated the following conditions apply:  $V_{IN} = 24\text{V}$ ,  $R_{ON} = 200\text{k}\Omega$ . See (Note 5).

FIGURE 1. Startup Sequence

## Functional Description

The LM25010 Step-Down Switching Regulator features all the functions needed to implement a low cost, efficient buck DC-DC converter capable of supplying in excess of 1A to the load. This high voltage regulator integrates an N-Channel buck switch, with an easy to implement constant on-time controller. It is available in the thermally enhanced LLP-10 and TSSOP-14EP packages. The regulator compares the feedback voltage to a 2.5V reference to control the buck switch, and provides a switch on-time which varies inversely with VIN. This feature results in the operating frequency remaining relatively constant with load and input voltage variations. The switching frequency can range from less than 100 kHz to 1.0 MHz. The regulator requires no loop compensation resulting in very fast load transient response. The valley current limit circuit holds the buck switch off until the free-wheeling inductor current falls below the current limit threshold, nominally set at 1.25A.

The LM25010 can be applied in numerous applications to efficiently step-down higher DC voltages. Features include:

Thermal shutdown, VCC under-voltage lock-out, gate drive under-voltage lock-out, and maximum duty cycle limit.

## Control Circuit Overview

The LM25010 employs a control scheme based on a comparator and a one-shot on-timer, with the output voltage feedback (FB) compared to an internal reference (2.5V). If the FB voltage is below the reference the buck switch is turned on for a time period determined by the input voltage and a programming resistor ( $R_{ON}$ ). Following the on-time the switch remains off for a fixed 260 ns off-time, or until the FB voltage falls below the reference, whichever is longer. The buck switch then turns on for another on-time period. Referring to the Block Diagram, the output voltage is set by R1 and R2. The regulated output voltage is calculated as follows:

$$V_{OUT} = 2.5V \times (R1 + R2) / R2 \quad (1)$$

The LM25010 requires a minimum of 25 mV of ripple voltage at the FB pin for stable fixed-frequency operation. If the output capacitor's ESR is insufficient additional series resistance may be required (R3 in the Block Diagram).

The LM25010 operates in continuous conduction mode at heavy load currents, and discontinuous conduction mode at light load currents. In continuous conduction mode current always flows through the inductor, never decaying to zero during the off-time. In this mode the operating frequency remains relatively constant with load and line variations. The minimum load current for continuous conduction mode is one-half the inductor's ripple current amplitude. The operating frequency in the continuous conduction mode is calculated as follows:

$$F_S = \frac{V_{OUT} \times (V_{IN} - 1.4V)}{1.18 \times 10^{-10} \times (R_{ON} + 1.4 \text{ k}\Omega) \times V_{IN}} \quad (2)$$

The buck switch duty cycle is equal to:

$$DC = \frac{t_{ON}}{t_{ON} + t_{OFF}} = t_{ON} \times F_S = \frac{V_{OUT}}{V_{IN}} \quad (3)$$

Under light load conditions, the LM25010 operates in discontinuous conduction mode, with zero current flowing through the inductor for a portion of the off-time. The operating frequency is always lower than that of the continuous conduction mode, and the switching frequency varies with load current. Conversion efficiency is maintained at a relatively high level at light loads since the switching losses diminish as the power delivered to the load is reduced. The discontinuous mode operating frequency is approximately:

$$F_S = \frac{V_{OUT}^2 \times L1 \times 1.4 \times 10^{20}}{R_L \times R_{ON}^2} \quad (4)$$

where  $R_L$  = the load resistance.

## Start-Up Bias Regulator ( $V_{CC}$ )

A high voltage bias regulator is integrated within the LM25010. The input pin ( $V_{IN}$ ) can be connected directly to

line voltages between 6V and 42V. Referring to the block diagram and the graph of  $V_{CC}$  vs.  $V_{IN}$ , when  $V_{IN}$  is between 6V and the bypass threshold (nominally 8.9V), the bypass switch (Q2) is on, and  $V_{CC}$  tracks  $V_{IN}$  within 100 mV to 150 mV. The bypass switch on-resistance is approximately 50 $\Omega$ , with inherent current limiting at approximately 100 mA. When  $V_{IN}$  is above the bypass threshold, Q2 is turned off, and  $V_{CC}$  is regulated at 7V. The  $V_{CC}$  regulator output current is limited at approximately 15 mA. When the LM25010 is shutdown using the RON/SD pin, the  $V_{CC}$  bypass switch is shut off, regardless of the voltage at  $V_{IN}$ .

When  $V_{IN}$  exceeds the bypass threshold, the time required for Q2 to shut off is approximately 2 - 3  $\mu$ s. The capacitor at VCC (C3) must be a minimum of 0.47  $\mu$ F to prevent the voltage at VCC from rising above its absolute maximum rating in response to a step input applied at  $V_{IN}$ . C3 must be located as close as possible to the LM25010 pins.

In applications with a relatively high input voltage, power dissipation in the bias regulator is a concern. An auxiliary voltage of between 7.5V and 14V can be diode connected to the VCC pin (D2 in Figure 2) to shut off the VCC regulator, reducing internal power dissipation. The current required into the VCC pin is shown in the Typical Performance Characteristics. Internally a diode connects VCC to  $V_{IN}$  requiring that the auxiliary voltage be less than  $V_{IN}$ .

The turn-on sequence is shown in Figure 1. When VCC exceeds the under-voltage lock-out threshold (UVLO) of 5.25V ( $t_1$  in Figure 1), the buck switch is enabled, and the SS pin is released to allow the soft-start capacitor (C6) to charge up. The output voltage  $V_{OUT}$  is regulated at a reduced level which increases to the desired value as the soft-start voltage increases ( $t_2$  in Figure 1).

20172716

FIGURE 2. Self Biased Configuration

## Regulation Comparator

The feedback voltage at the FB pin is compared to the voltage at the SS pin (2.5V,  $\pm 2\%$ ). In normal operation an on-time period is initiated when the voltage at FB falls below 2.5V. The buck switch conducts for the on-time programmed by  $R_{ON}$ ,

causing the FB voltage to rise above 2.5V. After the on-time period the buck switch remains off until the FB voltage falls below 2.5V. Input bias current at the FB pin is less than 5 nA over temperature.

## Over-Voltage Comparator

The feedback voltage at FB is compared to an internal 2.9V reference. If the voltage at FB rises above 2.9V the on-time is immediately terminated. This condition can occur if the input voltage, or the output load, changes suddenly. The buck switch remains off until the voltage at FB falls below 2.5V.

## ON-Time Control

The on-time of the internal buck switch is determined by the  $R_{ON}$  resistor and the input voltage ( $V_{IN}$ ), and is calculated as follows:

$$t_{ON} = \frac{1.18 \times 10^{-10} \times (R_{ON} + 1.4k)}{(V_{IN} - 1.4V)} + 67 \text{ ns} \quad (5)$$

The  $R_{ON}$  resistor can be determined from the desired on-time by re-arranging Equation 5 to the following:

$$R_{ON} = \frac{(t_{ON} - 67 \text{ ns}) \times (V_{IN} - 1.4V)}{1.18 \times 10^{-10}} - 1.4 \text{ k}\Omega \quad (6)$$

To set a specific continuous conduction mode switching frequency ( $F_S$ ), the  $R_{ON}$  resistor is determined from the following:

$$R_{ON} = \frac{V_{OUT} \times (V_{IN} - 1.4V)}{V_{IN} \times F_S \times 1.18 \times 10^{-10}} - 1.4 \text{ k}\Omega \quad (7)$$

20172718

FIGURE 3. Shutdown Implementation

## Current Limit

Current limit detection occurs during the off-time by monitoring the recirculating current through the internal current sense resistor ( $R_{SENSE}$ ). The detection threshold is 1.25A,  $\pm 0.25A$ . Referring to the Block Diagram, if the current into SGND during the off-time exceeds the threshold level the current limit comparator delays the start of the next on-time period. The next on-time starts when the current into SGND is below the threshold **and** the voltage at FB is below 2.5V. *Figure 4* illustrates the inductor current waveform during normal operation and during current limit. The output current  $I_O$  is the average of the inductor ripple current waveform. The Low Load Current waveform illustrates continuous conduction mode operation with peak and valley inductor currents below the current limit threshold. When the load current is increased (High Load Current), the ripple waveform maintains the same amplitude and frequency since the current falls below the current limit threshold at the valley of the ripple waveform. Note the average current in the High Load Current portion of *Figure 4* is above the current limit threshold. Since the current reduces below the threshold in the normal off-time each cycle, the start

of each on-time is not delayed, and the circuit's output voltage is regulated at the correct value. When the load current is further increased such that the lower peak would be above the threshold, the off-time is lengthened to allow the current to decrease to the threshold before the next on-time begins (Current Limited portion of *Figure 4*). Both  $V_{OUT}$  and the switching frequency are reduced as the circuit operates in a constant current mode. The load current ( $I_{OCL}$ ) is equal to the current limit threshold plus half the ripple current ( $\Delta I/2$ ). The ripple amplitude ( $\Delta I$ ) is calculated from:

$$t_{ON(min)} = \frac{V_{OUT} \times 300 \text{ ns}}{(V_{IN(min)} - V_{OUT})} \quad (8)$$

## Shutdown

The LM25010 can be remotely shut down by forcing the RON/SD pin below 0.7V with a switch or open drain device. See *Figure 3*. In the shutdown mode the SS pin is internally grounded, the on-time one-shot is disabled, the input current at  $V_{IN}$  is reduced, and the  $V_{CC}$  bypass switch is turned off. The  $V_{CC}$  regulator is not disabled in the shutdown mode. Releasing the RON/SD pin allows normal operation to resume. The nominal voltage at RON/SD is shown in the Typical Performance Characteristics. When switching the RON/SD pin, the transition time should be faster than one to two cycles of the regulator's nominal switching frequency.

of each on-time is not delayed, and the circuit's output voltage is regulated at the correct value. When the load current is further increased such that the lower peak would be above the threshold, the off-time is lengthened to allow the current to decrease to the threshold before the next on-time begins (Current Limited portion of *Figure 4*). Both  $V_{OUT}$  and the switching frequency are reduced as the circuit operates in a constant current mode. The load current ( $I_{OCL}$ ) is equal to the current limit threshold plus half the ripple current ( $\Delta I/2$ ). The ripple amplitude ( $\Delta I$ ) is calculated from:

$$\Delta I = \frac{(V_{IN} - V_{OUT}) \times t_{ON}}{L1} \quad (9)$$

The current limit threshold can be increased by connecting an external resistor ( $R_{CL}$ ) between SGND and ISEN.  $R_{CL}$  typically is less than  $1\Omega$ , and the calculation of its value is explained in the Applications Information section. If the current limit threshold is increased by adding  $R_{CL}$ , the maximum continuous load current should not exceed 1.5A, and the peak current out of the SW pin should not exceed 2A.

20172720

FIGURE 4. Inductor Current - Current Limit Operation

## N - Channel Buck Switch and Driver

The LM25010 integrates an N-Channel buck switch and associated floating high voltage gate driver. The peak current through the buck switch should not exceed 2A, and the load current should not exceed 1.5A. The gate driver circuit is powered by the external bootstrap capacitor between BST and SW (C4), which is recharged each off-time from  $V_{CC}$  through the internal high voltage diode. The minimum off-time, nominally 260 ns, ensures sufficient time during each cycle to recharge the bootstrap capacitor. A 0.022  $\mu$ F ceramic capacitor is recommended for C4.

## Soft-Start

The soft-start feature allows the regulator to gradually reach a steady state operating point, thereby reducing startup stresses and current surges. At turn-on, while  $V_{CC}$  is below the under-voltage threshold ( $t_1$  in Figure 1), the SS pin is internally grounded, and  $V_{OUT}$  is held at 0V. When  $V_{CC}$  exceeds the under-voltage threshold (UVLO) an internal 11.5  $\mu$ A current source charges the external capacitor (C6) at the SS pin to 2.5V ( $t_2$  in Figure 1). The increasing SS voltage at the non-inverting input of the regulation comparator gradually increases the output voltage from zero to the desired value. The soft-start feature keeps the load inductor current from reaching the current limit threshold during start-up, thereby reducing inrush currents.

An internal switch grounds the SS pin if  $V_{CC}$  is below the under-voltage lock-out threshold, or if the circuit is shutdown using the RON/SD pin.

## Thermal Shutdown

The LM25010 should be operated below the Maximum Operating Junction Temperature rating. If the junction temperature increases during a fault or abnormal operating condition, the internal Thermal Shutdown circuit activates typically at 175°C. The Thermal Shutdown circuit reduces power dissipation by disabling the buck switch and the on-timer. This feature helps prevent catastrophic failures from accidental device overheating. When the junction temperature reduces below approximately 155°C (20°C typical hysteresis), normal operation resumes.

## Applications Information

### EXTERNAL COMPONENTS

The procedure for calculating the external components is illustrated with a design example. Referring to the Block Diagram, the circuit is to be configured for the following specifications:

- $V_{OUT} = 5V$
- $V_{IN} = 6V$  to 40V
- $F_S = 175$  kHz
- Minimum load current = 200 mA
- Maximum load current = 1.0A
- Softstart time = 5 ms.

**R1 and R2:** These resistors set the output voltage, and their ratio is calculated from:

$$R1/R2 = (V_{OUT}/2.5V) - 1 \quad (10)$$

R1/R2 calculates to 1.0. The resistors should be chosen from standard value resistors in the range of 1.0 k $\Omega$  - 10 k $\Omega$ . A value of 1.0 k $\Omega$  will be used for R1 and for R2.

**$R_{ON}$ ,  $F_S$ :**  $R_{ON}$  can be chosen using Equation 7 to set the nominal frequency, or from Equation 6 if the on-time at a particular  $V_{IN}$  is important. A higher frequency generally means a smaller inductor and capacitors (value, size and cost), but higher switching losses. A lower frequency means a higher efficiency, but with larger components. Generally, if PC board space is tight, a higher frequency is better. The resulting on-time and frequency have a  $\pm 25\%$  tolerance. Using equation 7 at a nominal  $V_{IN}$  of 8V,

$$R_{ON} = \frac{5V \times (8V - 1.4V)}{8V \times 175 \text{ kHz} \times 1.18 \times 10^{-10}} - 1.4 \text{ k}\Omega = 198 \text{ k}\Omega$$

A value of 200 k $\Omega$  will be used for  $R_{ON}$ , yielding a nominal frequency of 161 kHz at  $V_{IN} = 6V$ , and 203 kHz at  $V_{IN} = 40V$ .

**L1:** The guideline for choosing the inductor value in this example is that it must keep the circuit's operation in continuous conduction mode at minimum load current. This is not a strict requirement since the LM25010 regulates correctly when in discontinuous conduction mode, although at a lower frequency. However, to provide an initial value for L1 the above guideline will be used.

FIGURE 5. Inductor Current

To keep the circuit in continuous conduction mode, the maximum allowed ripple current is twice the minimum load current, or 400 mAp-p. Using this value of ripple current, the inductor (L1) is calculated using the following:

$$L1 = \frac{V_{OUT} \times (V_{IN(max)} - V_{OUT})}{I_{OR} \times F_{S(min)} \times V_{IN(max)}} \quad (11)$$

where  $F_{S(min)}$  is the minimum frequency of 152 kHz (203 kHz - 25%) at  $V_{IN(max)}$ .

$$L1 = \frac{5V \times (40V - 5V)}{0.40A \times 152 \text{ kHz} \times 40V} = 72 \mu\text{H}$$

This provides a minimum value for L1 - the next higher standard value (100  $\mu\text{H}$ ) will be used. To prevent saturation, and possible destructive current levels, L1 must be rated for the peak current which occurs if the current limit and maximum ripple current are reached simultaneously ( $I_{PK}$  in Figure 4). The maximum ripple amplitude is calculated by re-arranging Equation 11 using  $V_{IN(max)}$ ,  $F_{S(min)}$ , and the minimum inductor value, based on the manufacturer's tolerance. Assume, for this exercise, the inductor's tolerance is  $\pm 20\%$ .

$$I_{OR(max)} = \frac{V_{OUT} \times (V_{IN(max)} - V_{OUT})}{L1_{min} \times F_{S(min)} \times V_{IN(max)}} \quad (12)$$

$$I_{OR(max)} = \frac{5V \times (40V - 5V)}{80 \mu\text{H} \times 152 \text{ kHz} \times 40V} = 360 \text{ mAp-p}$$

$$I_{PK} = I_{LIM} + I_{OR(max)} = 1.5A + 0.36A = 1.86A$$

where  $I_{LIM}$  is the maximum guaranteed current limit threshold. At the nominal maximum load current of 1.0A, the peak inductor current is 1.18A.

**R<sub>CL</sub>:** Since it is obvious that the lower peak of the inductor current waveform does not exceed 1.0A at maximum load current (see Figure 5), it is not necessary to increase the current limit threshold. Therefore  $R_{CL}$  is not needed for this exercise. For applications where the lower peak exceeds 1.0A, see the section entitled Increasing The Current Limit Threshold.

**C1:** This capacitor limits the ripple voltage at  $V_{IN}$  resulting from the source impedance of the supply feeding this circuit, and the on/off nature of the switch current into  $V_{IN}$ . At maximum load current, when the buck switch turns on, the current into  $V_{IN}$  steps up from zero to the lower peak of the inductor current waveform ( $I_{PK-}$  in Figure 5), ramps up to the peak val-

ue ( $I_{PK+}$ ), then drops to zero at turn-off. The average current into  $V_{IN}$  during this on-time is the load current. For a worst case calculation, C1 must supply this average current during the maximum on-time. The maximum on-time is calculated at  $V_{IN} = 6V$  using Equation 5, with a 25% tolerance added:

$$t_{ON(max)} = \left[ \frac{1.18 \times 10^{-10} \times (200k + 1.4k)}{6V - 1.4V} + 67 \text{ ns} \right] \times 1.25 = 6.5 \mu\text{s}$$

The voltage at  $V_{IN}$  should not be allowed to drop below 5.5V in order to maintain  $V_{CC}$  above its UVLO.

$$C1 = \frac{I_O \times t_{ON}}{\Delta V} = \frac{1.0A \times 6.5 \mu\text{s}}{0.5V} = 13 \mu\text{F}$$

Normally a lower value can be used for C1 since the above calculation is a worst case calculation which assumes the power source has a high source impedance. A quality ceramic capacitor with a low ESR should be used for C1.

**C2 and R3:** Since the LM25010 requires a minimum of 25 mVp-p of ripple at the FB pin for proper operation, the required ripple at  $V_{OUT}$  is increased by R1 and R2, and is equal to:

$$V_{RIPPLE} = 25 \text{ mVp-p} \times (R1 + R2)/R2 = 50 \text{ mVp-p}$$

This necessary ripple voltage is created by the inductor ripple current acting on C2's ESR + R3. First, the minimum ripple current, which occurs at minimum  $V_{IN}$ , maximum inductor value, and maximum frequency, is determined.

$$I_{OR(min)} = \frac{V_{OUT} \times (V_{IN(min)} - V_{OUT})}{L1_{max} \times F_{S(max)} \times V_{IN(min)}} \\ = \frac{5V \times (6V - 5V)}{120 \mu\text{H} \times 201 \text{ kHz} \times 6V} = 34.5 \text{ mAp-p} \quad (13)$$

The minimum ESR for C2 is then equal to:

$$ESR_{(min)} = \frac{50 \text{ mV}}{34.5 \text{ mA}} = 1.45\Omega$$

If the capacitor used for C2 does not have sufficient ESR, R3 is added in series as shown in the Block Diagram. The value chosen for C2 is application dependent, and it is recommended that it be no smaller than 3.3  $\mu\text{F}$ . C2 affects the ripple at  $V_{OUT}$ , and transient response. Experimentation is usually necessary to determine the optimum value for C2.

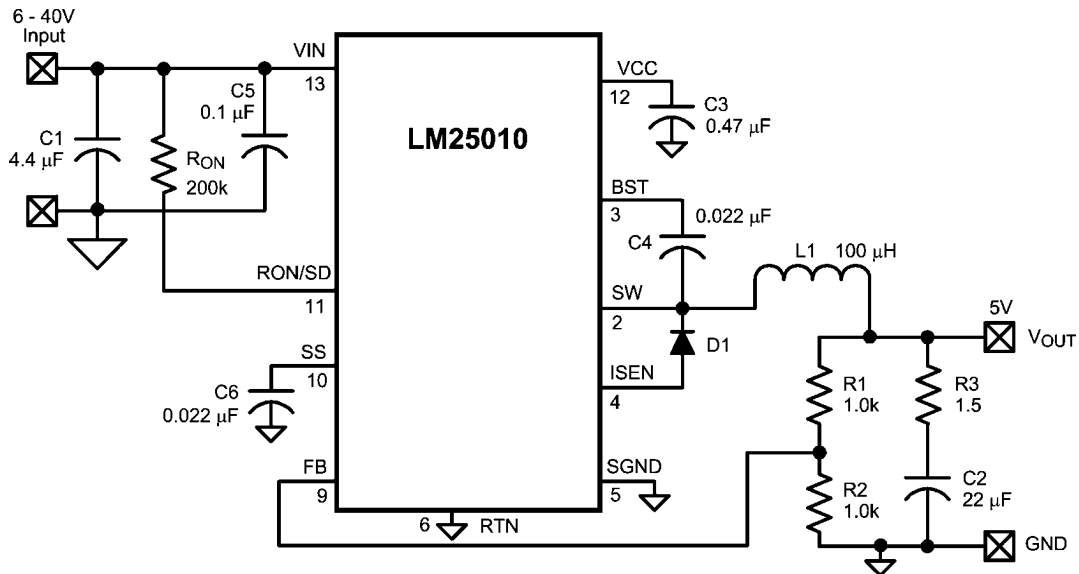

**C3:** The capacitor at the VCC pin provides noise filtering and stability, prevents false triggering of the  $V_{CC}$  UVLO at the buck switch on/off transitions, and limits the peak voltage at  $V_{CC}$  when a high voltage with a short rise time is initially applied at  $V_{IN}$ . C3 should be no smaller than  $0.47 \mu\text{F}$ , and should be a good quality, low ESR, ceramic capacitor, physically close to the IC pins.

**C4:** The recommended value for C4 is  $0.022 \mu\text{F}$ . A high quality ceramic capacitor with low ESR is recommended as C4 supplies the surge current to charge the buck switch gate at each turn-on. A low ESR also ensures a complete recharge during each off-time.

**C5:** This capacitor suppresses transients and ringing due to lead inductance at  $V_{IN}$ . A low ESR,  $0.1 \mu\text{F}$  ceramic chip capacitor is recommended, located physically close to the LM25010.

**C6:** The capacitor at the SS pin determines the soft-start time, i.e. the time for the reference voltage at the regulation comparator, and the output voltage, to reach their final value. The capacitor value is determined from the following:

$$C6 = \frac{t_{SS} \times 11.5 \mu\text{A}}{2.5\text{V}}$$

20172733

FIGURE 6. Example Circuit

For a 5 ms softstart time, C6 calculates to  $0.022 \mu\text{F}$ .

**D1:** A Schottky diode is recommended. Ultra-fast recovery diodes are not recommended as the high speed transitions at the SW pin may inadvertently affect the IC's operation through external or internal EMI. The diode should be rated for the maximum  $V_{IN}$  (40V), the maximum load current (1A), and the peak current which occurs when current limit and maximum ripple current are reached simultaneously ( $I_{PK}$  in Figure 4), previously calculated to be 1.86A. The diode's forward voltage drop affects efficiency due to the power dissipated during the off-time. The average power dissipation in D1 is calculated from:

$$P_{D1} = V_F \times I_O \times (1 - D)$$

where  $I_O$  is the load current, and D is the duty cycle.

#### FINAL CIRCUIT

The final circuit is shown in Figure 6, and its performance is shown in Figures 7 & 8. Current limit measured approximately 1.3A.

Item	Description	Value
C1	Ceramic Capacitor	(2) 2.2 $\mu$ F, 50V
C2	Ceramic Capacitor	22 $\mu$ F, 16V
C3	Ceramic Capacitor	0.47 $\mu$ F, 16V
C4, C6	Ceramic Capacitor	0.022 $\mu$ F, 16V
C5	Ceramic Capacitor	0.1 $\mu$ F, 50V
D1	Schottky Diode	60V, 2A
L1	Inductor	100 $\mu$ H
R1	Resistor	1.0 k $\Omega$
R2	Resistor	1.0 k $\Omega$
R3	Resistor	1.5 $\Omega$
R <sub>ON</sub>	Resistor	200 k $\Omega$
U1	National Semi LM25010

FIGURE 7. Efficiency vs Load Current and  $V_{IN}$   
Circuit of Figure 6

20172737

FIGURE 8. Frequency vs  $V_{IN}$   
Circuit of Figure 6

**MINIMUM LOAD CURRENT**

The LM25010 requires a minimum load current of 500  $\mu$ A. If the load current falls below that level, the bootstrap capacitor (C4) may discharge during the long off-time, and the circuit

will either shutdown, or cycle on and off at a low frequency. If the load current is expected to drop below 500  $\mu$ A in the application, R1 and R2 should be chosen low enough in value so they provide the minimum required current at nominal  $V_{OUT}$ .

**LOW OUTPUT RIPPLE CONFIGURATIONS**

For applications where low output voltage ripple is required the output can be taken directly from the low ESR output capacitor (C2) as shown in Figure 9. However, R3 slightly degrades the load regulation. The specific component values, and the application determine if this is suitable.

20172715

FIGURE 9. Low Ripple Output

Where the circuit of Figure 9 is not suitable, the circuits of Figure 10 or Figure 11 can be used.

20172748

FIGURE 10. Low Output Ripple Using a Feedforward Capacitor

In Figure 10, Cff is added across R1 to AC-couple the ripple at  $V_{OUT}$  directly to the FB pin. This allows the ripple at  $V_{OUT}$  to be reduced, in some cases considerably, by reducing R3. In the circuit of Figure 6, the ripple at  $V_{OUT}$  ranged from 50 mVp-p at  $V_{IN} = 6V$  to 285 mVp-p at  $V_{IN} = 40V$ . By adding a

1000 pF capacitor at C<sub>ff</sub> and reducing R<sub>3</sub> to 0.75Ω, the V<sub>OUT</sub> ripple was reduced by 50%, ranging from 25 mVp-p to 142 mVp-p.

20172749

**FIGURE 11. Low Output Ripple Using Ripple Injection**

To reduce V<sub>OUT</sub> ripple further, the circuit of *Figure 11* can be used. R<sub>3</sub> has been removed, and the output ripple amplitude is determined by C<sub>2</sub>'s ESR and the inductor ripple current. RA and CA are chosen to generate a 40-50 mVp-p sawtooth at their junction, and that voltage is AC-coupled to the FB pin via CB. In selecting RA and CA, V<sub>OUT</sub> is considered a virtual ground as the SW pin switches between V<sub>IN</sub> and -1V. Since the on-time at SW varies inversely with V<sub>IN</sub>, the waveform amplitude at the RA/CA junction is relatively constant. R<sub>1</sub> and R<sub>2</sub> must typically be increased to more than 5k each to not significantly attenuate the signal provided to FB through CB. Typical values for the additional components are RA = 200k, CA = 680 pF, and CB = 0.01 μF.

#### INCREASING THE CURRENT LIMIT THRESHOLD

The current limit threshold is nominally 1.25A, with a minimum guaranteed value of 1.0A. If, at maximum load current, the lower peak of the inductor current (I<sub>PK-</sub> in *Figure 5*) exceeds 1.0A, resistor R<sub>CL</sub> must be added between SGND and ISEN to increase the current limit threshold to equal or exceed that lower peak current. This resistor diverts some of the recirculating current from the internal sense resistor so that a higher current level is needed to switch the internal current limit comparator. I<sub>PK-</sub> is calculated from:

$$I_{PK-} = I_{O(max)} - \frac{I_{OR(min)}}{2} \quad (14)$$

where I<sub>O(max)</sub> is the maximum load current, and I<sub>OR(min)</sub> is the minimum ripple current calculated using Equation 13. R<sub>CL</sub> is calculated from:

$$R_{CL} = \frac{1.0A \times 0.11\Omega}{I_{PK-} - 1.0A} \quad (15)$$

where 0.11Ω is the minimum value of the internal resistance from SGND to ISEN. The next smaller standard value resistor should be used for R<sub>CL</sub>. With the addition of R<sub>CL</sub>, and when the circuit is in current limit, the upper peak current out of the SW pin (I<sub>PK</sub> in *Figure 4*) can be as high as:

$$I_{PK} = \frac{1.5A \times (150 \text{ m}\Omega + R_{CL})}{R_{CL}} + I_{OR(MAX)}$$

where I<sub>OR(max)</sub> is calculated using Equation 12. The inductor L<sub>1</sub> and diode D<sub>1</sub> must be rated for this current. If I<sub>PK</sub> exceeds 2A, the inductor value must be increased to reduce the ripple amplitude. This will necessitate recalculation of I<sub>OR(min)</sub>, I<sub>PK-</sub>, and R<sub>CL</sub>.

Increasing the circuit's current limit will increase power dissipation and the junction temperature within the LM25010. See the next section for guidelines on this issue.

#### PC BOARD LAYOUT and THERMAL CONSIDERATIONS

The LM25010 regulation, over-voltage, and current limit comparators are very fast, and will respond to short duration noise pulses. Layout considerations are therefore critical for optimum performance. The layout must be as neat and compact as possible, and all the components must be as close as possible to their associated pins. The two major current loops have currents which switch very fast, and so the loops should be as small as possible to minimize conducted and radiated EMI. The first loop is that formed by C<sub>1</sub>, through the VIN to SW pins, L<sub>1</sub>, C<sub>2</sub>, and back to C<sub>1</sub>. The second loop is that formed by D<sub>1</sub>, L<sub>1</sub>, C<sub>2</sub>, and the SGND and ISEN pins. The ground connection from C<sub>2</sub> to C<sub>1</sub> should be as short and direct as possible, preferably without going through vias. Directly connect the SGND and RTN pin to each other, and they should be connected as directly as possible to the C<sub>1</sub>/C<sub>2</sub> ground line without going through vias. The power dissipation within the IC can be approximated by determining the total conversion loss (P<sub>IN</sub> - P<sub>OUT</sub>), and then subtracting the power losses in the free-wheeling diode and the inductor. The power loss in the diode is approximately:

$$P_{D1} = I_O \times V_F \times (1-D)$$

where I<sub>O</sub> is the load current, V<sub>F</sub> is the diode's forward voltage drop, and D is the duty cycle. The power loss in the inductor is approximately:

$$P_{L1} = I_O^2 \times R_L \times 1.1$$

where R<sub>L</sub> is the inductor's DC resistance, and the 1.1 factor is an approximation for the AC losses. If it is expected that the internal dissipation of the LM25010 will produce high junction temperatures during normal operation, good use of the PC board's ground plane can help considerably to dissipate heat. The exposed pad on the IC package bottom should be soldered to a ground plane, and that plane should both extend from beneath the IC, and be connected to exposed ground plane on the board's other side using as many vias as possible. The exposed pad is internally connected to the IC substrate. The use of wide PC board traces at the pins, where possible, can help conduct heat away from the IC. The four No Connect pins on the TSSOP package are not electrically connected to any part of the IC, and may be connected to ground plane to help dissipate heat from the package. Judicious positioning of the PC board within the end product, along with the use of any available air flow (forced or natural convection) can help reduce the junction temperature.

### LIFE SUPPORT POLICY

**NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS PRIOR WRITTEN APPROVAL OF THE CHIEF EXECUTIVE OFFICER AND GENERAL COUNSEL OF NATIONAL SEMICONDUCTOR CORPORATION.** As used herein:

Life support devices or systems are devices which (a) are intended for surgical implant into the body, or (b) support or sustain life and whose failure to perform when properly used in accordance with instructions for use provided in the labeling can be reasonably expected to result in a significant injury to the user. A critical component is any component in a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system or to affect its safety or effectiveness.

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
